

# Mathematics for finance

## Aim

The course motivates and illustrates the role and limitations of mathematics in quantitative finance. We recall basic concepts of calculus and linear algebra, within the context of financial applications. We also illustrate and generalize essential ideas in normed and inner product spaces, which are essential in both financial theory and numerical methods. Everything is illustrated from three related points of view: theory, applications, and numerical implementation in MATLAB.

## Content

- *Motivations*. Basic problems in quantitative finance: portfolio optimization, risk management, asset pricing.
- *Calculus*. Continuity and differentiability. Approximating functions by Taylor expansions. Applications: finite differences, price sensitivities.
- *Linear algebra*. Linear spaces. Matrices, eigenvalues, quadratic forms. Semidefinite quadratic forms.
- *Norms, distances, and inner products*. Defining norms and inner products for vector and matrices. Projection on subspaces. Applications: linear regression, regularized linear regression.
- *Convex analysis*: convex sets and functions; concave functions and risk aversion; convex cones; separation theorems; Farkas lemma.
- *Optimization theory*: unconstrained optimization (gradient, subgradient, black box); classical Lagrange methods; KKT conditions.
- *Applications*:
  - Mean-variance portfolio optimization.
  - Foundations of mathematical finance: pricing by no arbitrage; state prices; complete and incomplete markets.
- *Stochastic calculus*. A preview of stochastic differential equations and Ito's lemma. Application to BSM model.
